## 1 Likelihood Ratio Test

## 1.1 One Sample Normal, Mean and Variance Unknown

Let  $X_1, \ldots, X_n \stackrel{\text{iid}}{\sim} \mathcal{N}(\mu, \sigma^2)$ , with unknown mean and variance. We wish to test  $H_0: \mu = \mu_0$  against  $H_1: \mu \neq \mu_0$  with the likelihood ratio test, which has test statistic

$$\Lambda(\mu, \sigma^2 | X) = \frac{\max_{\Omega_0} \mathcal{L}(\mu, \sigma^2 | X)}{\max_{\Omega} \mathcal{L}(\mu, \sigma^2 | X)},$$

where  $\Omega_0 = \{(\mu, \sigma^2) \mid \mu = \mu_0, \sigma^2 > 0\}$ , and  $\Omega = \{(\mu, \sigma^2) \mid \mu \in \mathbb{R}, \sigma^2 > 0\}$ , and  $X = (X_1, X_2, \dots, X_n)$  (the vector of the sample).

The likelihood is

$$\mathcal{L}(\mu, \sigma^2 | X) = (2\pi\sigma^2)^{-n/2} \exp\left\{-\frac{1}{2\sigma^2} \sum_{i=1}^n (X_i - \mu)^2\right\}.$$

The log likelihood is

$$\ell(\mu, \sigma^2) = -\frac{n}{2}\log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \sum_{i=1}^n (X_i - \mu)^2.$$

**Assuming**  $H_0$ , we have  $\mu = \mu_0$ , so the maximum likelihood estimate  $\hat{\sigma}_0^2$  of  $\sigma^2$  over the null space is found by maximizing  $\ell$  wrt  $\sigma^2$  with  $\mu = \mu_0$ .

$$\frac{d\ell(\mu_0, \sigma^2)}{d\sigma^2} = -\frac{1}{2} \left[ \frac{n}{\sigma^2} - \frac{1}{(\sigma^2)^2} \sum (X_i - \mu_0)^2 \right]$$
$$0 = n\hat{\sigma}_0^2 - \sum (X_i - \mu_0)^2$$
$$\hat{\sigma}_0^2 = \frac{1}{n} \sum_{i=1}^n (X_i - \mu_0)^2.$$

The MLEs of the parameters over the full parameter space are found by maximizing  $\ell(\mu, \sigma^2)$ , where both parameters are allowed to vary. The MLE of  $\mu$  is

$$\frac{\partial \ell(\mu, \sigma^2)}{\partial \mu} = \frac{1}{\sigma^2} \sum_{i=1}^n (X_i - \mu) \tag{1}$$

$$0 = \sum_{i=1}^{n} (X_i - \hat{\mu}) \tag{2}$$

$$\hat{\mu} = \frac{1}{n} \sum_{i=1}^{n} X_i.$$
 (3)

The MLE of  $\sigma^2$  follows from the derivation used for the null estimate, replacing  $\mu$  by  $\hat{\mu}$ :

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n (X_i - \hat{\mu})^2.$$

The likelihood ratio test statistic is then

$$\Lambda(X) = \frac{(2\pi\hat{\sigma}_0^2)^{-n/2} \exp\left\{\frac{-1}{2\hat{\sigma}_0^2} \sum (X_i - \mu_0)^2\right\}}{(2\pi\hat{\sigma}^2)^{-n/2} \exp\left\{\frac{-1}{2\hat{\sigma}^2} \sum (X_i - \hat{\mu})^2\right\}}.$$

Recognizing that  $\hat{\sigma}^2 = \frac{1}{n} \sum (X_i - \hat{\mu})^2$  and similar for  $\hat{\sigma}_0^2$ , the terms inside the exponential cancel to -n/2, and the exponential terms in the numerator and denominator cancel, giving

$$\Lambda(X) = \left(\frac{\hat{\sigma}_0^2}{\hat{\sigma}^2}\right)^{-n/2}.$$

We reject  $H_0$  when  $\Lambda(X)$  is small; equivalently, we reject  $H_0$  when

$$\frac{\hat{\sigma}_0^2}{\hat{\sigma}^2} = \frac{\sum (X_i - \mu_0)^2}{\sum (X_i - \hat{\mu})^2}$$

is large.

Recalling the identity  $\sum (X_i - \mu_0)^2 = \sum (X_i - \bar{X})^2 - \sum (\bar{X} - \mu_0)^2$ , we can write

$$\begin{split} \frac{\hat{\sigma}_0^2}{\hat{\sigma}^2} &= \frac{\sum (X_i - \mu_0)^2}{\sum (X_i - \hat{\mu})^2} \\ &= \frac{\sum (X_i - \bar{X})^2 + \sum (\bar{X} - \mu_0)^2}{\sum (X_i - \bar{X})^2} \\ &= 1 + \frac{n(\bar{X} - \mu_0)^2}{\sum (X_i - \bar{X})^2}. \end{split}$$

Thus, the LRT will reject  $H_0$  when  $\frac{n(\bar{X}-\mu_0)^2}{\sum (X_i-\bar{X})^2}$  is large.

Similar to our derivation of the distribution of the sample variance, we know  $n(\bar{X} - \mu_0)^2/\sigma^2 \stackrel{H_0}{\sim} \chi_1^2$ , and  $\sum (X_i - \bar{X})^2/\sigma^2 \stackrel{H_0}{\sim} \chi_{n-1}^2$ .

Using the fact that the numerator and denominator are independent (verify this is true for yourself), we can conclude with the following test statistic and reference distribution:

$$T(X) = \frac{n(\bar{X} - \mu_0)^2}{\sum (X_i - \bar{X})^2 / (n - 1)} \stackrel{H_0}{\sim} F_{1, n - 1}.$$

The null hypothesis will be rejected when T(X) is large. For a test with significance level  $\alpha$ ,  $H_0$  will be rejected when  $T(X) > F_{1,n-1}(1-\alpha)$ . That is, the rejection region is defined by the  $1-\alpha$  percentile of the  $F_{1,n-1}$  distribution.
